1 Propositional Logic

Why are we interested in logic as computer scientists? Our aim is to develop languages to formulate specifications and to model systems in such a way that we can *reason* about them *formally*.

Example. Consider the following argument: If the plane arrives late and there are no taxis at the airport, then Alice is late for her appointment. Alice is not late for her appointment. The plane did arrive late. *Therefore*, there were taxis at the airport.

We can reason intuitively that the argument is valid. If there are no taxis, Alice would be late to the appointment since the plane was late. Since she was not late, it must be the case that there were taxis at the airport. So the sentence after the 'therefore' *logically follows* from the sentences before it.

Example. If the sun is shining and John does not have his sun creme with him, then he will get sunburn. John is not sunburn. The sun is shining. *Therefore*, John has his sun creme with him.

Again, the argument is valid. Notice, that both arguments actually have the same logical structure:

If p and not q, then r. Not r. p. Therefore, q.

By only considering the *logical structure* of the sentences instead of what the sentence really means, we are able to perform reasoning formally and automatically. Therefore, we need languages able to express sentences in such a way that brings out their logical structure. In this course, we will discuss the languages of propositional logic and predicate logic. We will begin with the language of propositional logic.

1.1 Declarative Sentences

Propositional logic, like most varieties of logic, is only concerned with sentences that make statements, so called *declarative sentences*, or *propositions*. Declarative sentences state a fact, or describe a state of affairs. A declarative sentence can be declared as *true* or *false*. It must be one or the other. (It cant be both, nor can it be undefined). True and false are referred to as *truth values*.

Example. Examples for declarative sentences are:

- 10 divided by 5 is 3.
- Mozart was born in Austria.
- Santa Clause lives on the North Pole.
- Its raining in Graz right now.
- Alle meine Entchen schwimmen auf dem See.

All of these sentences can be determined to be either true or false. The first sentence can easily be demonstrated to be false, since it holds that "10 divided by 5 is 2". The second and third sentence need to be examined more closely. You need to know who Mozart and Santa Clause are and you need to gather evidence about them to find out whether or not those statements are true. The fourth sentence has no absolute truth value, but at any given point in time it is either true or false. The fifth sentence demonstrates that declarative sentences can be made in any language. Similarly to the fourth sentence this one may or may not be true, depending on who is saying it and when.

Non-declarative sentences are, amongst others, questions, orders, and greetings.

Example. Examples for non-declerative sentences are:

- Do you like ice cream?
- Take the dog for a walk!
- Hello!
- May the force be with you!

1.2 Syntax of Propositional Logic

Propositional logic formulas consist of *atomic propositions*, *logical operators*, and *parentheses*.

Atomic propositions

Atomic propositions are declarative sentences, or parts of declarative sentences, that can be assigned a truth value and cannot be split up into two or more

sentences that can be assigned a truth value themselves. For brevity, atomic propositions are shortened to a single lower case letter.

An atomic proposition can be represented by a *propositional symbols*, or *propositional variable* such as p, p_1 or q.

Example.

p : It is Sunday.
q : Students have to present their solutions at the exercise classes.

These statements can be true or false and cannot be shortened any further, so they are atomic propositions.

Logical Operators

We form compound statements from atomic statements, by joining them using connectives.

Example. As an example, consider the sentence:

John is happy *and* he his hungry.

This is a compound statement: the word and is an example of a connective. The atomic propositions are p : "John is happy" and p : "John is hungry".

The symbols $\neg$ (not), $\wedge$ (and), $\vee$ (or), $\rightarrow$ (implies), and $\leftrightarrow$ (equivalent) are used to represent the connectives and are called the *logical operators*.

Example. Given the sentence:

"Two straight lines can either be parallel or intersecting, but not both."

To model this sentence as a formula, we define the atomic propositions $p :=$ "lines are parallel", and $q :=$ "lines are intersecting". Then, the sentence can be modelled by the formula $\varphi := (p \vee q) \wedge \neg(p \wedge q)$.

Example. Given the sentence:

"Tomorrow is Tuesday, if and only if today is Monday."

To model this sentence as a formula, we define the atomic propositions $p :=$ "today is Monday", and $q :=$ "tomorrow is Tuesday". Then, the sentence can be modelled by the formula $\varphi := (p \leftrightarrow q) \equiv (p \rightarrow q) \wedge (q \rightarrow p)$.

Example. Let k be some specific number. The atomic propositions are defined by $a :=$ "k is even", $b :=$ "k is greater than seven", and $c :=$ "k is prime". Using the defined atomic propositions, we can formally model the following sentences:

- "Number k is even or greater than 7" is modelled by $a \vee b$
- "If k is both even and prime, then in particular it is even" is modelled by $a \wedge c \rightarrow a$
- "Either k is even, or k is prime, and not both" is modelled by $(a \vee c) \wedge \neg(a \wedge c)$

Definition of the Syntax of Propositional Logic

Formulas in propositional logic are strings over the alphabet of atomic propositions, logical operators and parentheses. However, the string $pq()(\wedge)$ does not make a lot of of sense as far as propositional logic is concerned. We have to define those strings which we want to call formulas. We call such formulas well-formed.

Definition. The *well-formed formulas* of propositional logic are those which we obtain by using the construction rules below, and only those, finitely many times:

- Every propositional symbol is a well-formed formula. We use p, p_1, $p_2 \ldots$, q, q_1, $q_2 \ldots$ as propositional symbols.
- For any well-formed formula φ, the following is also a well-formed formula: $\neg\varphi$.
- For any two well-formed formulas φ and ψ, the following are also well-formed formulas: $\varphi \wedge \psi$, $\varphi \vee \psi$, $\varphi \to \psi$ and $\varphi \leftrightarrow \psi$.
- Any well-formed formula φ may be enclosed in parentheses and will still be a well-formed formula, i.e., (φ).

Note: No other string of symbols is a propositional formula.

The definition of well-formed formulas in propositional logic can also be defined using a grammar in Backus Naur form (BNF). In that form, the above definition reads more compactly as:

$$\varphi := < \text{automic proposition} > \mid \varphi \wedge \varphi \mid \varphi \vee \varphi \mid \neg\varphi \mid \varphi \to \varphi \mid \varphi \leftrightarrow \varphi \mid (\varphi)$$

Parentheses and Operator Precedence

Parentheses determine evaluation order. The operator precedence define how strongly an operator is binding to its sub-formulas. Precedence rules can be given:

$$\text{Highest} \quad \neg \quad \wedge \quad \vee \quad \to \quad \leftrightarrow \quad \text{Lowest}$$

For example, $p \wedge q \vee r \to p$ evaluates as $((p \wedge q) \vee r) \to p$. Associativity rules can be given:

$$\text{Associate to the left: } \vee \wedge$$
$$\text{Associate to the right: } \to \leftrightarrow$$

Example. The formula $p \wedge q \wedge r \to p \to r$ evaluates as $((p \wedge q) \wedge r) \to (p \to r)$.

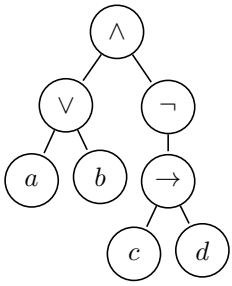
The operator precedence is very useful in reducing the number of parentheses. For example, the $\neg$ operator has highest precedence. So, e.g., $\neg p \wedge q$ evaluates as $(\neg p) \wedge q$, and, for the other evaluation order, you would write $\neg(p \wedge q)$.

Parse Trees

How can we show that a string is a well-formed formula? Consider the following formula:

$$\varphi \coloneqq (a \vee b) \wedge (\neg(c \to d))$$

The easiest way to verify whether some formula φ is a well-formed formula is by trying to draw its parse tree. The parse tree for φ is given below.



At its top level, the formula is a conjunction. The left sub-formula is a disjunction and the top level connective of the right sub-formula is first a negation followed by an implication.

To verify if ϕ is well-formed, we need to check whether all leaves are atomic variables. All other nodes are labeled with logical operators. In the case of $\neg$ there is only one subtree coming out of that node. In the cases $\wedge$, $\vee$, $\to$, and $\leftrightarrow$ we must have two subtrees.

When drawing the parse tree do not forget about the operator precedence to decide on the current top level connective.

1.3 Semantics of Propositional Logic

So far, we have discussed propositional logical formulas. We noted that formulas derive from declarative sentences, or statements. We would now like to determine whether a formula is *true* or *false* based on the truth/falsehood of the statements that comprise the formula and the meaning of the logical operators. Truth is a *semantic* notion, in that it ascribes a type of *meaning* to certain formulas. There are different notations for truth values, see Table 1.1.

true	**false**
T	F
1	0
$\top$	$\bot$

Figure 1.1: Different notations of truth values.

The semantics of propositional logic are the rules we give for our propositional connectives. They are defined in the *truth tables* below, as illustrated in Figure 1.2 - Figure 1.6.

φ	ψ	$\varphi \wedge \psi$
F	F	F
F	T	F
T	F	F
T	T	T

φ	ψ	$\varphi \leftrightarrow \psi$
F	F	T
F	T	F
T	F	F
T	T	T

Figure 1.6: Truth table for equivalence.

How can you check that a formula ϕ and a formula ψ are semantically equivalent? For example, to understand the meaning (= the semantics) of an impli-

cation, consider the formula $\phi \coloneqq p \to q$ and the formula $\psi \coloneqq \neg p \vee q$. By using the truth tables for $\neg$ and $\vee$ you can check that $p \to q$ evaluates to T if and only if $\neg p \vee q$ does so. Since this is the case, this means that φ and ψ are are semantically equivalent.

What is the caveat in using truth tables? Given a formula φ which contains the propositional atoms $p_1, p_2, \ldots, p_n$. The truth table of φ has 2^n lines. Each line listing a possible combination of truth values for $p_1, p_2, \ldots, p_n$. Since the number of lines grows exponentially, truth tables are not practical for large formulas.

Models

Models are also called *valuations*, *interpretations*, or *assignments*.

Definition. A *model* $\mathcal{M}$ of a propositional formula φ is an assignment of each propositional variable in φ to a truth value.

Example. Consider the formula $\varphi \coloneqq \neg p \wedge q$. The map which assigns F to p and T to q is a model $\mathcal{M}$ for φ, i.e,: $\mathcal{M} : p = F, q = T$.

Furthermore, we distinguish between:

- *Satisfying Model:* truth assignment such that the formula resolves to *true*.
- *Falsifying Model:* truth assignment such that the formula resolves to *false*.

Let $\mathcal{M}$ be a model for a formula φ. Formally, we use the following notation:

- $\varphi^{\mathcal{M}}$: The formula φ is evaluated under the model $\mathcal{M}$.
- $\mathcal{M} \vDash \varphi$: The model satisfies the formula.
- $\mathcal{M} \nvDash \varphi$: The model does not satisfy the formula.

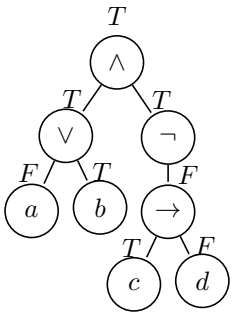
We call $\vDash$ the *semantic entailment* relation.

Evaluation of a Logical Formula under a given Model

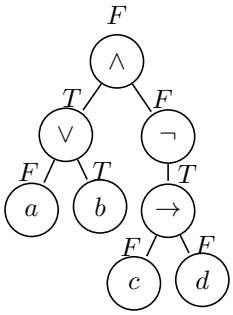
How can we determine the truth value of a formula φ for a given model $\mathcal{M}$? Given the meaning of the atomic propositions defined by $\mathcal{M}$, we can use the parse tree of φ to propagate the truth values upwards. The associated truth value of the root is the truth value of φ.

Example. Let $\varphi \coloneqq (a \vee b) \wedge (\neg(c \to d))$ and $\mathcal{M}_1 \coloneqq a = F,\ b = T,\ c = T,\ d = F$.

The parse tree if given below. We assign the truth values of the atomic propositions to the lowest level. Then the truth values are propagated upwards, e.g., since $F \vee T = T$, the left sub-tree evaluates to true. $T \to F$ evaluates to false, etc. Finally, to evaluate the meaning of φ, we compute $T \wedge T$ which is T. Formally, we have $\varphi^{\mathcal{M}_1} = T$, or $\mathcal{M}_1 \vDash \varphi$.



Example. Let us consider the same formula $\varphi \coloneqq (a \vee b) \wedge (\neg(c \to d))$ under for a different model $\mathcal{M}_2 \coloneqq a = F,\ b = T,\ c = F,\ d = F$. As illustrated below, the formula now evaluates to false. Formally, we have $\varphi^{\mathcal{M}_2} = F$, or $\mathcal{M}_2 \not\models \varphi$.



1.4 Semantic Entailment, Equivalence, Satisfiability and Validity

Next, we discuss elementary concepts of semantics in propositional logic: the concepts of semantic entailment, semantic equivalence, validity, and satisfiability.

Semantic Entailment

We talk of semantic entailment, if a formula is a special case of another formula.

The symbol for semantic entailment is the same symbol that is used to show that a model satisfies a formula. If the formula φ entails the formula ψ we write:

$$\varphi \models \psi.$$

We say that a formula φ semantically entails a formula ψ, if any model that satisfies φ also satisfies ψ, i.e., we have $\varphi \models \psi$ if $\mathcal{M} \models \varphi$ implies $\mathcal{M} \models \psi$.

Definition. Let φ and ψ be formulas of propositional logic. We say that $\varphi \vDash \psi$ if and only if every model $\mathcal{M}$ that satisfies φ ($\mathcal{M} \vDash \varphi$) also satisfies ψ ($\mathcal{M} \vDash \psi$).

Example. It holds that $a \vDash a \vee b$, $a \vee b \nvDash a$, $(p \wedge q) \vDash p$, and $(p \vee q) \nvDash p$.

Example. It holds that $\bot \vDash \varphi$. The definition of semantic entailment requires that all models that satisfy the entailing formula also satisfy the entailed formula. Since a contradiction does not have any satisfying models, a contradiction entails any possible formula.

Figure 1.7 gives a visual representation of the semantic entailment relation. In the illustration we have the following area encodings.

- Big circles represents the sets of all possible models.
- Dark gray areas represent the models that satisfy formula φ.
- Light gray areas represent the models that satisfy formula ψ.
- Gridded areas represent the models that satisfy formulas φ and ψ.
- White areas represent the models that neither satisfy formula φ nor ψ.

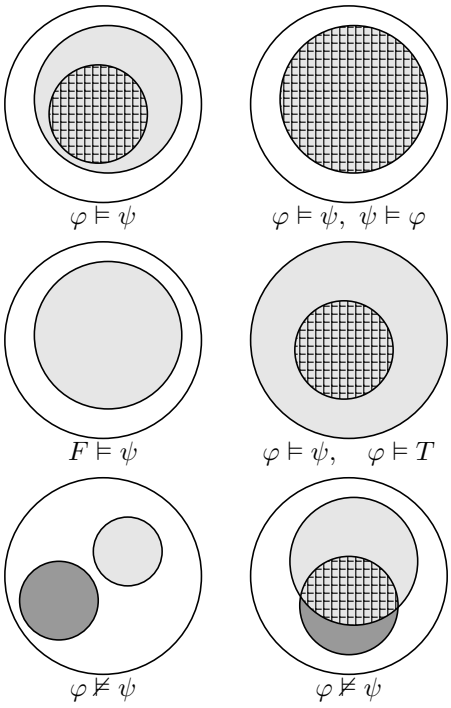


Figure 1.7: Visualisation of the semantic entailment relation.

Semantic Equivalence

Two formulas φ and ψ are said to be equivalent if they have the same *meaning*. If both formulas consist of the same variables, this can be verified by checking the entries in their truth table. For example, the formula $p \to q$ and $\neg p \vee q$ have the same truth table and are therefore semantically equivalent. However, the truth table of $p \wedge q \to p$ has 4 lines and the truth table of $r \vee \neg r$ has only 2 lines, but since both formulas always evaluate to true they are nevertheless equivalent.

For this reason, the semantic equivalence of formulas is defined via the semantic entailment relation.

Definition. Let φ and ψ be formulas of propositional logic. We say that φ and ψ are semantically equivalent if and only if $\varphi \vDash \psi$ and $\psi \vDash \varphi$ holds.

In that case we write $\varphi \equiv \psi$.

Example. $a \to b \equiv \neg b \to \neg a$ and $a \to b \equiv \neg a \vee b$.

Validity

A formula is called *valid*, if the formula evaluates to *true* under all possible models.

Definition. Let φ be a formula of propositional logic. We call φ valid if $\vDash \varphi$ holds.

A valid formula is also called a *tautology*.

Example. The formula $\varphi := (p \vee \neg p)$ is valid.

Example. It holds that $\varphi \vDash T$. All possible models satisfy a tautology. Thus, any formula entails true.

Satisfiability

Another important question in logic is the question whether there exists a model under which the formula evaluates to true.

Definition. Given a formula φ in propositional logic, we say that φ is *satisfiable* if it has a valuation/model in which is evaluates to *true*.

Example. Let $\varphi := (p \vee \neg q) \to p$. φ is satisfiable since it evaluated to *true* under the model $\mathcal{M} := p = T, q = T$. Note, that φ is not valid, since it evaluates to *false* under $\mathcal{M} := p = F, q = F$.

A formula that is *not* satisfiable is called a *contradiction*, i.e., the formula evaluates to *false* under all possible models.

Example. The formula $\varphi := (p \wedge \neg p)$ is not satisfiable.

A simple way of checking satisfiablity or validity for small formulas is using its truth table.

Example. Consider the formula $\varphi \coloneqq a \wedge \neg(b \rightarrow c)$. Its truth table is shown in Figure 1.8. The formula is satisfiable since there is an entry at the table that is *true*. The formula is not valid since there are entries at the table that are *false*.

a	b	c	$b \rightarrow c$	$\neg(b \rightarrow c)$	φ
F	F	F	T	F	F
F	F	T	T	F	F
F	T	F	F	T	F
F	T	T	T	F	F
T	F	F	T	F	F
T	F	T	T	F	F
T	T	F	F	T	T
T	T	T	T	F	F

Figure 1.8: Truth table of $\varphi \coloneqq a \wedge \neg(b \rightarrow c)$.

1.5 Encoding Example

In order to solve a problem using propositional logic, we need to find a proper encoding in propositional logic such that a satisfying assignment of the formula represents a solution for our problem. A satisfying assignment (if one exists) can be automatically found by a SAT solver. A SAT solver is a tool that takes as input a propositional formula and outputs either a satisfying assignment to the variables used in the formula if the formula can be satisfied or UNSAT if it can not.

Example. We use propositional logic to solve Sudoku. Rules: A Sudoku grid consists of a 9x9 square, which is partitioned into nine 3x3 squares. The goal is to write one number from 1 to 9 in each cell in such a way, that each row, each column, and each 3x3-square contains each number exactly once. Usually several numbers are already given.

	6		7			1	5	
		3	9			8		
		2	3				4	9
		7			4			
	4			9			8	
			1			4		
6	7				9	3		
		9			2	5		
	2	8			7		6	

Sudoku

In order to model SUDOKU, we first need to define the propositional variables that we want to use in our formula.

One way to solve the problem is to define variables x_{ijk} for every row i, for every column j, and for every value k. This encoding yields to 729 variables ranging from x_{111} to x_{999}. Next, we need to define the constraints for the rows, the columns, the 3x3-squares and the predefined numbers.

- *Row-constraints: If* a cell in a row has a certain value, *then* no other cell in that row can have that value. For each i, and each k we have:

$$x_{i1k} \rightarrow \neg x_{i2k} \wedge \neg x_{i3k} \wedge ... \wedge \neg x_{i9k}$$
$$x_{i2k} \rightarrow \neg x_{i1k} \wedge \neg x_{i2k} \wedge ... \wedge \neg x_{i9k}$$
$$\vdots$$
$$x_{i9k} \rightarrow \neg x_{i1k} \wedge \neg x_{i2k} \wedge ... \wedge \neg x_{i8k}$$

- *Column-constraints: If* a cell in a column has a certain value, *then* no other cell in that column can have that value. For each j, and each k we have:

$$x_{1jk} \rightarrow \neg x_{2jk} \wedge \neg x_{3jk} \wedge ... \wedge \neg x_{9jk}$$
$$x_{2jk} \rightarrow \neg x_{1jk} \wedge \neg x_{2jk} \wedge ... \wedge \neg x_{9jk}$$
$$\vdots$$
$$x_{9jk} \rightarrow \neg x_{1jk} \wedge \neg x_{2jk} \wedge ... \wedge \neg x_{8jk}$$

- *Square-constraints: If* a cell in a 3x3 square has a certain value, *then* no other cell in that square can have that value. For the first square, we have for each k:

$$x_{11k} \rightarrow \neg x_{12k} \wedge \neg x_{13k} \wedge \neg x_{21k} \wedge \neg x_{22k} \wedge \neg x_{23k} \wedge \neg x_{31k} \wedge \neg x_{32k} \wedge \neg x_{33k}$$
$$\vdots$$
$$x_{33k} \rightarrow \neg x_{11k} \wedge \neg x_{12k} \wedge \neg x_{13k} \wedge \neg x_{21k} \wedge \neg x_{22k} \wedge \neg x_{23k} \wedge \neg x_{31k} \wedge \neg x_{32k}$$

  The constraints for the remaining squares are similar.

- *Predefined-number-constraints:* If a cell has a predefined value, we need to set the corresponding variable to true, e.g., the cell in the fifth row and the fifth column has the value 9. Therefore we have

$$x_{559}.$$

- *Cell-constraints:* Each cell must contain a number ranging from one to nine. For each i, and each j we have

$$x_{ij1} \vee x_{ij2} \vee ... \vee x_{ij9}.$$

  On its own, this constraint would allow for a cell to have more than one value. However, this is not possible due to the other constraints.

To construct the final propositional formula, all constraints need to be connected via conjunctions. A satisfying assignment for the final formula represents one possible solution for the Sudoku puzzle. In case that there does not exists a solution, the SAT sovler would return UNSAT.

1.6 Exercises

1.6.1 Examples

Example 1. Determine which of the following sentences are declarative sentences and translate them into propositional formulas.

(a) If Mike prepares a salad, then the salad has lettuce and tomatoes and no cucumber.

(b) Nice to meet you!

(c) Taylor will either play tennis, or soccer, or both.

(d) Why do dogs bark?

(e) Graz University of Technology is placed in Austria.

(f) Alex will either take a bath, or a shower, but not both.

(g) If it is winter, then if lakes are frozen, ice skating is possible.

(h) Fluffy is Joe's pet cat if and only if fluffy is a cat and Joe is Fluffy's owner.

Example 2. Draw the parse trees and the truth tables for the following formulas. Determine their satisfiability and validity. Determine for each formula whether it is a tautology, a contradiction, or neither.

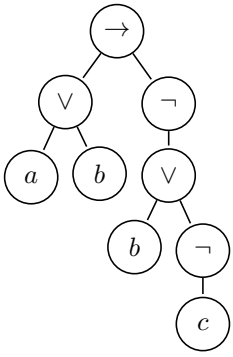
(a) $\varphi \coloneqq \neg a \wedge a \to b \vee a$

(b) $\varphi \coloneqq \neg a \wedge (a \to b \vee a)$

(c) $\varphi \coloneqq \neg(a \wedge a \to b \vee a)$

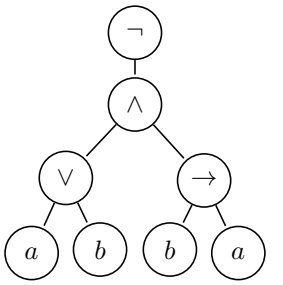
(d) $\varphi \coloneqq \neg(a \wedge a \to b) \vee a$

Example 3. Write down the formulas the following parse trees are based on. For each tree, find a model that satisfies it and a model that falsifies it.



(a)

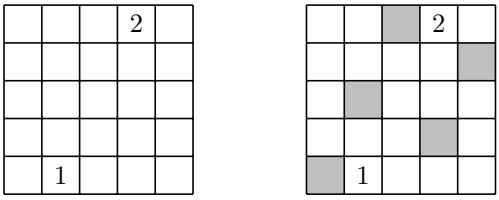
(b)



Example 4. Determine, which of the following formulas entail each other.

φ	ψ	ϕ
F	F	F
T	T	F
F	F	F
T	T	T
F	F	F
F	T	F
T	T	T
T	T	F

Example 5. Describe the Latin Square Puzzle using propositional logic. In the Latin Square Puzzle one has to color cells in an (nŒn) grid such that there is exactly one colored cell in each row and each column. Furthermore, colored cells must not be adjacent to each other (also not diagonally). Numbers contained in certain cells of the grid indicate the exact number of colored cells that have to be adjacent (including diagonally) to it. Numbered cells can contain the numbers 0, 1, 2 and cannot be colored.



Example Latin Square Puzzle and its solution

You should find propositional formulas which describe the puzzle and which could be used to solve it. Focus on explaining the concept of the formulas. You do not have to explicitly list all formulas and you do not have to solve the puzzle.

Hints: Use propositional atoms $c_{i,j}$, $c_{i,j,0}$, $c_{i,j,1}$,$c_{i,j,2}$ to represent each cell of the $(n \times n)$ game board. If $c_{i,j}$ has the value *True*, the cell i, j is colored, otherwise it is not colored.

If $c_{i,j,x}$ has the value *True*, the cell i, j contains the number x.

Express the following constraints:

(a) There is exactly one colored cell in row i.

(b) No colored cells are adjacent to each other.

(c) No numbered cells can be colored.

(d) Numbered cells are adjacent to the indicated amount of colored cells.

1.6.2 Solutions

Solution 1.

(a) This is a declarative sentence.

p : Mike prepares a salad.
q : Mike's salad has lettuce.
r : Mike's salad has tomatoes.
s : Mike's salad has cucumber.

$$p \to q \wedge r \wedge \neg s$$

(b) This is no declarative sentence.

(c) This is a declarative sentence.

p : Taylor will play tennis.
q : Taylor will play soccer.

$$p \vee q$$

(d) This is no declarative sentence.

(e) This is a declarative sentence.

$$\begin{array}{c} p: \\ \text{Graz University of Technology is placed in Austria.} \\ p \end{array}$$

(f) This is a declarative sentence.

p : Alex will take a bath.
q : Alex will take a shower.

$$(p \wedge \neg q) \vee (\neg p \wedge q)$$

(g) This is a declarative sentence.

p : It is winter.
q : Lakes are frozen.
r : Ice skating is possible.

$$p \to q \to r$$

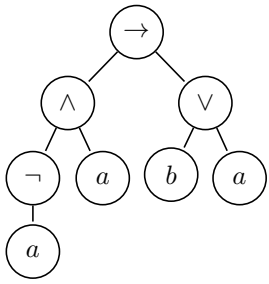
(h) This is a declarative sentence.

p : Fluffy is Joe's pet cat.
q : Fluffy is a cat.
r : Joe is Fluffy's owner.

$$(p \to q \wedge r) \wedge (q \wedge r \to p)$$

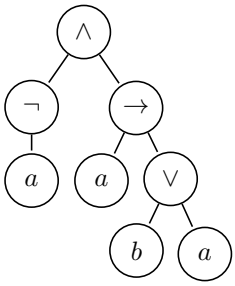
Solution 2. (a) This formula is a tautology, i.e., it is both satisfiable and valid.

a	b	$\neg a$	$\neg a \wedge a$	$b \vee a$	$\neg a \wedge a \rightarrow b \vee a$
F	F	T	F	F	T
F	T	T	F	T	T
T	F	F	F	T	T
T	T	F	F	T	T



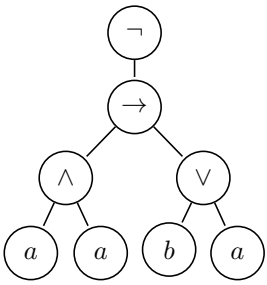
(b) This formula is satisfiable but not valid.

a	b	$\neg a$	$b \vee a$	$a \rightarrow b \vee a$	$\neg a \wedge (a \rightarrow b \vee a)$
F	F	T	F	T	T
F	T	T	T	T	T
T	F	F	T	T	F
T	T	F	T	T	F



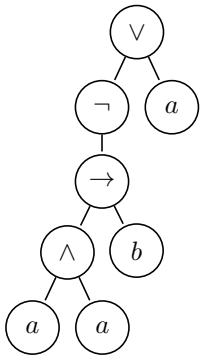
(c) This formula is a contradiction. It is neither satisfiable nor valid.

a	b	$a \wedge a$	$b \vee a$	$a \wedge a \rightarrow b \vee a$	$\neg(a \wedge a \rightarrow b \vee a)$
F	F	F	F	T	F
F	T	F	T	T	F
T	F	T	T	T	F
T	T	T	T	T	F



(d) This formula is satisfiable but not valid.

a	b	$a \wedge a$	$a \wedge a \to b$	$\neg(a \wedge a \to b)$	$\neg(a \wedge a \to b) \vee a$
F	F	F	T	F	F
F	T	F	T	F	F
T	F	T	T	F	T
T	T	T	T	F	T



Solution 3. (a) Formula:

$$\varphi = a \vee b \to \neg(b \vee \neg c)$$

Models:

$$\mathcal{M} : a = F,\ b = F,\ c = F \vee T \qquad \mathcal{M} \vDash \varphi$$
$$\mathcal{M} : a = T,\ b = F,\ c = T \qquad \mathcal{M} \vDash \varphi$$
$$\mathcal{M} : a = F \vee T,\ b = T,\ c = T \vee F \qquad \mathcal{M} \nvDash \varphi$$
$$\mathcal{M} : a = T,\ b = F,\ c = F \vee T \qquad \mathcal{M} \nvDash \varphi$$

(b) Formula:

$$\varphi = \neg((a \vee b) \wedge (b \to a)$$

Models:

$$\mathcal{M} : a = F,\ b = F \vee T \qquad \mathcal{M} \vDash \varphi$$
$$\mathcal{M} : a = T,\ b = F \vee true \qquad \mathcal{M} \nvDash \varphi$$

Solution 4. $\varphi \vDash \psi, \quad \phi \vDash \psi, \quad \phi \vDash \varphi$

Solution 5.

(a) For all rows i:
$(c_{i,1} \wedge \neg c_{i,2} \wedge \neg c_{i,3} \wedge ... \wedge \neg c_{i,n}) \vee$
$(\neg c_{i,1} \wedge c_{i,2} \wedge \neg c_{i,3} \wedge ... \wedge \neg c_{i,n}) \vee$
$... \vee$
$(\neg c_{i,1} \wedge \neg c_{i,2} \wedge ... \wedge \neg c_{i,n-1} \wedge c_{i,n})$

(b) For all cells i, j: $c_{i,j} \rightarrow (\neg c_{i+1,j-1} \wedge \neg c_{i+1,j+1})$
other options are covered by (Solution 5.a) and
$(p \rightarrow \neg q) \leftrightarrow (q \rightarrow \neg p)$

(c) For all cells i, j: $c_{i,j,0} \vee c_{i,j,1} \vee c_{i,j,2} \rightarrow \neg c_{i,j}$

(d) For all cells i, j:
$(c_{i,j,0} \rightarrow \neg c_{i-1,j-1} \wedge \neg c_{i-1,j} \wedge ... \wedge \neg c_{i,j-1}) \wedge$
$(c_{i,j,1} \rightarrow (c_{i-1,j-1} \wedge \neg c_{i,j+1} \wedge \neg c_{i+1,j+1} \wedge \neg c_{i+1,j}) \vee$
$(c_{i-1,j} \wedge \neg c_{i+1,j-1} \wedge \neg c_{i+1,j+1}) \vee ...) \wedge$
$(c_{i,j,2} \rightarrow (c_{i-1,j-1} \wedge (c_{i,j+1} \vee c_{i+1,j+1} \vee c_{i+1,j})) \vee$
$(c_{i-1,j+1} \wedge (c_{i+1,j} \vee c_{i+1,j-1} \vee c_{i,j-1})) \vee ...)$

1.6.3 Self-Evaluation

These examples will be solved online during class.

Example 1. Consider a formula φ in propositional logic. In the following list, tick all statements that are true.

- ☐ If φ is not satisfiable, $\neg\varphi$ is valid.
- ☐ If φ is valid, $\neg\varphi$ is not valid.
- ☐ If φ is valid, $\neg\varphi$ is not satisfiable.
- ☐ If φ is not valid, $\neg\varphi$ is satisfiable.

Example 2. Consider a formula φ in propositional logic. Let the number of propositional variables in φ be n. How many lines does the truth table for φ have?

Example 3. Consider the propositional formula $\varphi = (p \wedge q) \rightarrow (q \vee \neg r)$.

(a) Fill out the truth table for φ (and its sub-formulas). Write **T** for true and **F** for false.

p	q	r	$p \wedge q$	$\neg r$	$q \vee \neg r$	φ
F	**F**	**F**				
F	**F**	**T**				
F	**T**	**F**				
F	**T**	**T**				
T	**F**	**F**				
T	**F**	**T**				
T	**T**	**F**				
T	**T**	**T**				

(b) Is φ satisfiable?

- ☐ Yes
- ☐ No

(c) Is φ valid?

- ☐ Yes
- ☐ No

Example 4. Consider the propositional formulas $\varphi = (p \to q) \vee \neg r$, and $\psi = (\neg r \wedge p) \vee (\neg q \to \neg r)$.

(a) Fill out the truth table for φ and ψ (and their subformulas). Write **T** for true and **F** for false.

p	q	r	$\neg q$	$\neg r$	$p \to q$	$\neg r \wedge p$	$\neg q \to \neg r$	φ	ψ
F	**F**	**F**							
F	**F**	**T**							
F	**T**	**F**							
F	**T**	**T**							
T	**F**	**F**							
T	**F**	**T**							
T	**T**	**F**							
T	**T**	**T**							

(b) Which of the formulas is satisfiable?

- ☐ None
- ☐ Only φ
- ☐ Only ψ
- ☐ Both

(c) Which of the formulas is valid?

- ☐ None
- ☐ Only φ
- ☐ Only ψ
- ☐ Both

(d) Is φ equivalent to ψ?

- ☐ Yes
- ☐ No

(e) Which of the two formulas φ and ψ entails the other?

- ☐ None of the formulas entails the other.
- ☐ φ entails ψ, but not vice versa.
- ☐ ψ entails φ, but not vice versa.
- ☐ Both formulas entail the respective other.

(f) How can you decide whether or not a formula entails another formula, based on their truth tables?

(g) Why are truth tables, in general, not used to determine entailment between (large) formulas?

Example 5. Consider the propositional formula $\varphi = \neg(\neg p \vee q) \rightarrow (p \wedge \neg r)$.

(a) Is φ satisfiable?

☐ Yes

☐ No

(b) Is φ valid?

☐ Yes

☐ No

(c) Draw the parse tree of φ.

(d) Pick an (arbitrary) assignment for all variables in φ. Using the parse tree of φ, determine whether or not the assignment satisfies φ.
Remark: You should assign a truth value to each node of the parse tree.

(e) Find a propositional formula ψ that is syntactically different from φ, but semantically equivalent to φ. Show the semantic equivalence of φ and ψ using truth tables.
